Asymmetric Dimethylarginine Impairs Angiogenic Progenitor Cell Function in Patients With Coronary Artery Disease Through a MicroRNA-21–Dependent Mechanism

Felix Fleissner, Virginija Jazbutyte, Jan Fiedler, Shashi K. Gupta, Xiaoke Yin, Qingbo Xu, Paolo Galuppo, Susanne Kneitz, Manuel Mayr, Georg Ertl, Johann Bauersachs, Thomas Thum

Rationale: The endogenous nitric oxide synthase inhibitor asymmetrical dimethylarginine (ADMA) is increased in patients with coronary artery disease and may regulate function of circulating angiogenic progenitor cells (APCs) by small regulatory RNAs.

Objectives: To study the role of microRNAs in ADMA-mediated impairment of APCs.

Methods and Results: By using microarray analyses, we established microRNA expression profiles of human APCs.

We used ADMA to induce APC dysfunction and found 16 deregulated microRNAs. We focused on *miR-21*, which was 3-fold upregulated by ADMA treatment. Overexpression of *miR-21* in human APCs impaired migratory capacity. To identify regulated *miR-21* targets, we used proteome analysis, using difference in-gel electrophoresis followed by mass spectrometric analysis of regulated proteins. We found that transfection of *miR-21* precursors significantly repressed superoxide dismutase 2 in APCs, which resulted in increased intracellular reactive oxygen species concentration and impaired nitric oxide bioavailability. *MiR-21* further repressed sprouty-2, leading to Erk Map kinase–dependent reactive oxygen species formation and APC migratory defects. Small interference RNA–mediated superoxide dismutase 2 or sprouty-2 reduction also increased reactive oxygen species formation and impaired APC migratory capacity. ADMA-mediated reactive oxygen species formation and APC dysfunction was rescued by *miR-21* blockade. APCs from patients with coronary artery disease and high ADMA plasma levels displayed >4-fold elevated *miR-21* levels, low superoxide dismutase 2 expression, and impaired migratory capacity, which could be normalized by *miR-21* antagonism.

Conclusions: We identified a novel *miR-21*–dependent mechanism of ADMA-mediated APC dysfunction. *MiR-21* antagonism therefore emerges as an interesting strategy to improve dysfunctional APCs in patients with coronary artery disease. (*Circ Res*. 2010;107:138–143.)

Key Words: endothelial progenitor cells ■ microRNAs ■ ADMA ■ coronary artery disease ■ oxidative stress

The endogenous nitric oxide synthase (NOS) inhibitor asymmetrical dimethylarginine (ADMA) is a major risk factor in patients with coronary artery disease (CAD).^{1–3} Functionally, ADMA induces dysfunction of circulating angiogenic progenitor cells (APCs) (early outgrowth endothelial progenitor cells or circulating angiogenic cells)⁴ and impairs neovascularization⁵ by direct inhibition of the endothelial NOS.⁶ NO plays a crucial role in mobilization, differentiation, and function of APCs,^{7,8} whereas oxidative stress impairs APC function.^{9,10}

MicroRNAs (miRNAs) are a class of highly conserved, noncoding short RNA molecules that regulate a large portion of the genome. MiRNAs play a crucial role in cardiac

biology, and miRNA dysregulation is often found in cardiovascular diseases.¹¹ Knockdown of the miRNA-processing enzyme Dicer in endothelial cells reduces the formation of capillary-like structures by profound dysregulation of angiogenesis-related genes,¹² and Dicer-deficient mice die from impaired blood vessel formation and vascularization.¹³ Recently, miRNAs have been shown to be interesting therapeutic targets in cardiovascular disease, including cardiac fibrosis¹⁴ and postmyocardial remodeling.¹⁵

In this study, we hypothesized that ADMA exerts effects on the miRNA transcriptome in APCs, leading to functional impairment in vitro and in patients with CAD. In addition, we aimed to identify miRNA-regulated targets and to improve

Non-standard Abbreviations and Acronyms	
APC	angiogenic progenitor cell
ADMA	asymmetric dimethylarginine
CAD	coronary artery disease
miR	microRNA
miRNA	microRNA
NOS	nitric oxide synthase
ROS	reactive oxygen species
siRNA	small interfering RNA
SPRY2	Sprouty2
SOD2	superoxide dismutase type II

APC function by modulation of an miRNA-dependent mechanism.

Methods

We used microarray-based miRNA transcriptome analyses¹⁴ and a proteome approach¹⁶ to identify miRNA-dependent mechanisms underlying ADMA-mediated dysfunction of human APCs. An expanded Methods section is available in the Online Data Supplement at <http://circres.ahajournals.org>.

Results

MicroRNA Expression in Human APCs

To study miRNA expression in human APCs (for characterization, see the Online Data Supplement) a microarray-based approach to screen for the expression of 312 different human miRNAs was used. MiRNAs of the *let-7* family, *miR-21*, -16, -191, -223, 23a, and -23b, were most easily detectable (Online Table I and Figure 1a). The miRNA expression profile of APCs showed a high degree of similarity with that of human umbilical vein endothelial cells and human coronary arterial endothelial cells, although *miR-223* was enriched in APCs, whereas *miR-126* expression was much higher in mature endothelial cells (see Online Table I).

Table. Deregulated miRNAs in APCs by ADMA Treatment

ID	Fold Change	P	Absolute Expression Levels	
			Control	ADMA, 1 μmol/L

MicroRNA Expression in ADMA-Induced APC Dysfunction

ADMA mediates APC dysfunction at least in part by impairment of NO bioavailability.⁴ We thus monitored APC function by testing migratory capacity and used ADMA to induce APC dysfunction. ADMA reduced APC migration in a dose-dependent manner (1 to 10 μmol/L, Figure 1b). We used a pathophysiologically relevant concentration of ADMA (1 μmol/L)⁴ and performed miRNA transcriptome analysis before and 24 hours after addition of ADMA. ADMA treatment resulted in significant changes of the miRNA transcriptome in APCs. Ten miRNAs were significantly increased (Table). Importantly, the relatively high baseline expression level of miR-21 was further 2.7-fold increased by

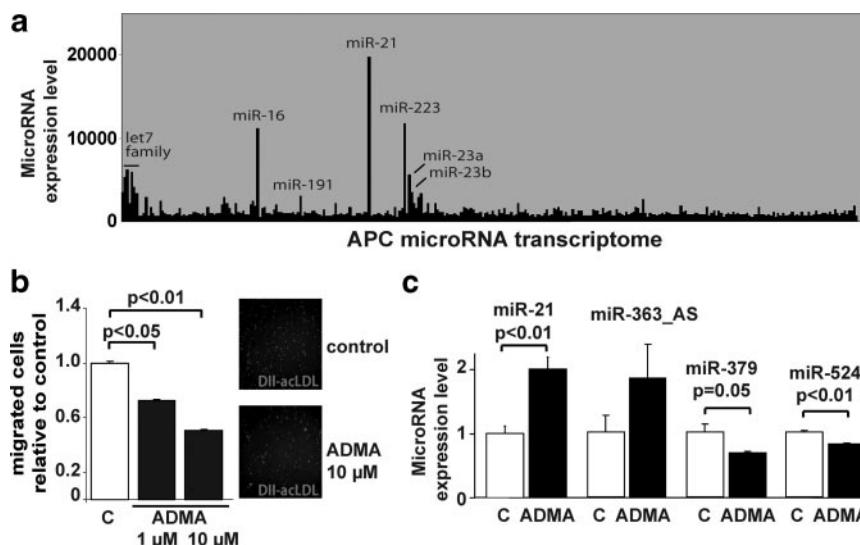

Figure 1. Microarray-based determination of 312 human miRNAs in isolated APCs. a, Microarray data are based on n=3 to 4 different donors per cell type. A detailed list of absolute and normalized miRNA expression levels is shown in Online Table I. **b,** Migrated APCs after treatment (24 hours) with different concentrations of ADMA (1 to 10 μmol/L) relative to controls (C). **c,** Real-time PCR-based validation of several miRNAs (in relation to RNU6b) after treatment of APCs with ADMA (1 μmol/L, 24 hours). Data are expressed as means±SEM, n=3 to 4 per experiment/group. The complete data set of ADMA-altered miRNAs is shown in the Table.

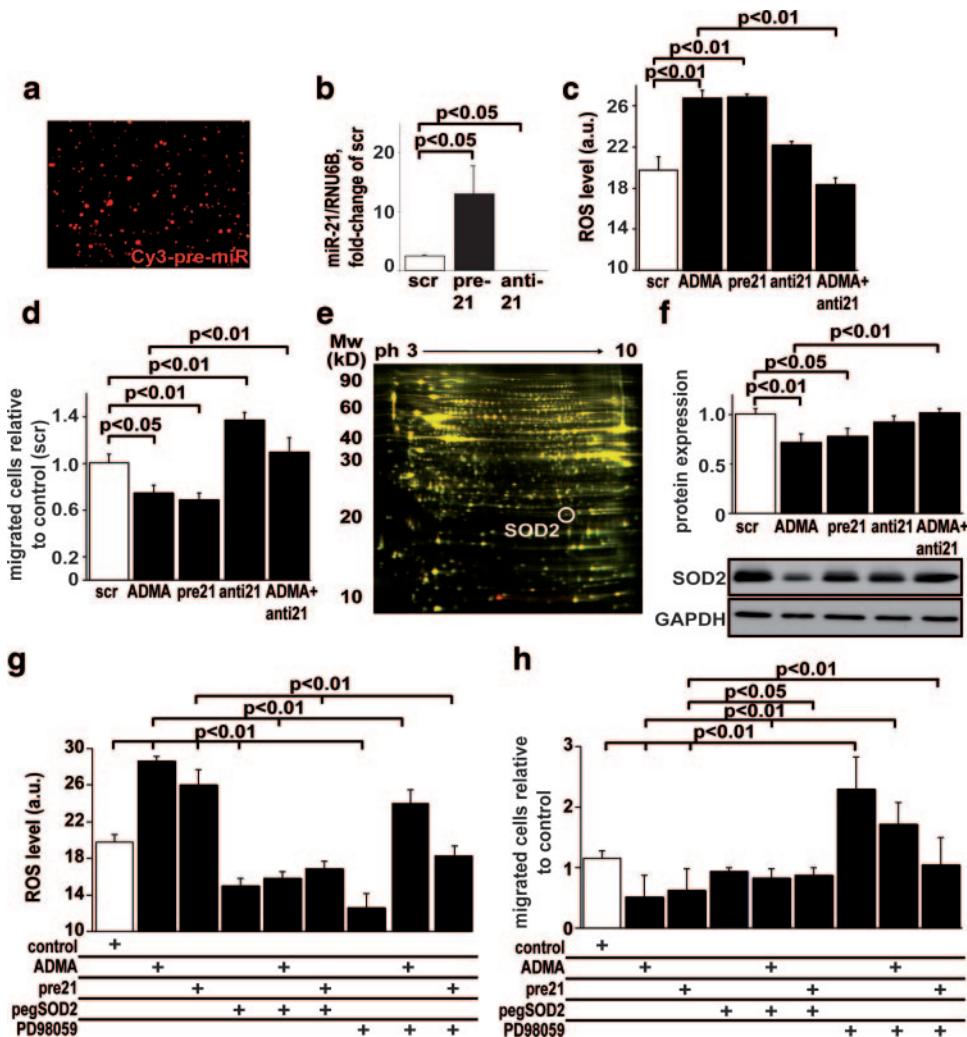

Figure 2. Identification of miR-21 targets in APCs. **a**, Efficient transfection of APCs with Cy3-labeled miRNA precursors to APCs. **b**, miR-21/IRNU6b levels in APCs 72 hours after transfection with scrambled miRNAs (scr), miR-21 precursors (pre-21), or miR-21 inhibitors (anti-21). **c**, ROS concentration and migratory capacity (**d**) in APCs 72 hours after ADMA treatment and/or miR-21 modulation. **e**, Difference in-gel electrophoresis of human umbilical vein endothelial cells 72 hours after treatment with scrambled miRNAs or miR-21 precursors (each 100 nmol/L). Derepressed SOD2 is highlighted by white circle. A detailed list of regulated proteins is shown in Online Table II. **f**, Protein expression of SOD2 and GAPDH in APCs 72 hours after ADMA treatment and/or miR-21 modulation. Impact of the addition of pegylated SOD2 (pegSOD2) or the Erk Map kinase inhibitor PD98059 on ROS formation (**g**) or migratory capacity (**h**) of APCs. Data are expressed as means \pm SEM, n=3 to 6 per experiment/group.

ADMA treatment. Six miRNAs were significantly repressed by ADMA (Table). Regulation of several miRNAs was validated by miRNA-specific real-time RT-PCR (Figure 1c). We focused our further studies on the role of *miR-21* in APC function.

ADMA Increases Reactive Oxygen Species (ROS) Formation, Reduces NO Bioavailability, and Impairs APC Migration by *miR-21*

To identify *miR-21* function in APCs, we transfected *miR-21* precursors and inhibitors. Transfection efficiency in APCs and mature endothelial cells was high, based on detection of Cy3-labeled miRNA precursors and increase in *miR-21* expression, whereas transfection of *miR-21* inhibitors significantly lowered *miR-21* expression (Figure 2a and 2b and data not shown). *miR-21* overexpression and ADMA treatment resulted in increased ROS concentration (Figure 2c), reduced NO bioavailability (Online Figure I), and impaired migratory capacity of human APCs, whereas *miR-21* inhibition blocked such ADMA-mediated effects (Figure 2c and 2d and Online Figures I and II). There were no significant changes of *miR-21* modulation on APC apoptosis (Online Figure III).

miR-21 Regulates Superoxide Dismutase 2 (SOD2) and the Erk Map Kinase Inhibitor Sprouty2 in APCs

To screen for *miR-21* targets, we first used a difference in-gel electrophoresis approach followed by tandem mass spectrometry analysis to search for deregulations in the proteome of human umbilical vein endothelial cells (Figure 2e). *miR-21* overexpression led to altered expression ($P<0.05$) of 51 proteins 24 hours after treatment (Figure 2e and Online Figure IV and Online Table II). The strongest repression was found for superoxide dismutase type II (SOD2), a protein that is involved in oxidative stress defense. We validated the *miR-21*-mediated decrease in SOD2 protein expression in cultured APCs by Western blotting (Figure 2f). ADMA also reduced SOD2 protein expression in APCs, which could be blocked by cotransfection with anti-*miR-21* (Figure 2f). In addition, SOD2 mRNA expression was repressed by ADMA treatment (Online Figure V). Of note, the 3'UTR of SOD2 displays no *miR-21* binding site, based on 3 different bioinformatic prediction tools (PicTar, TargetScan, and miRBase), suggesting an indirect mechanism of action. To study the role of SOD2 in APCs, we treated cells with pegylated SOD2, which resulted in reduced ROS formation and prevention of

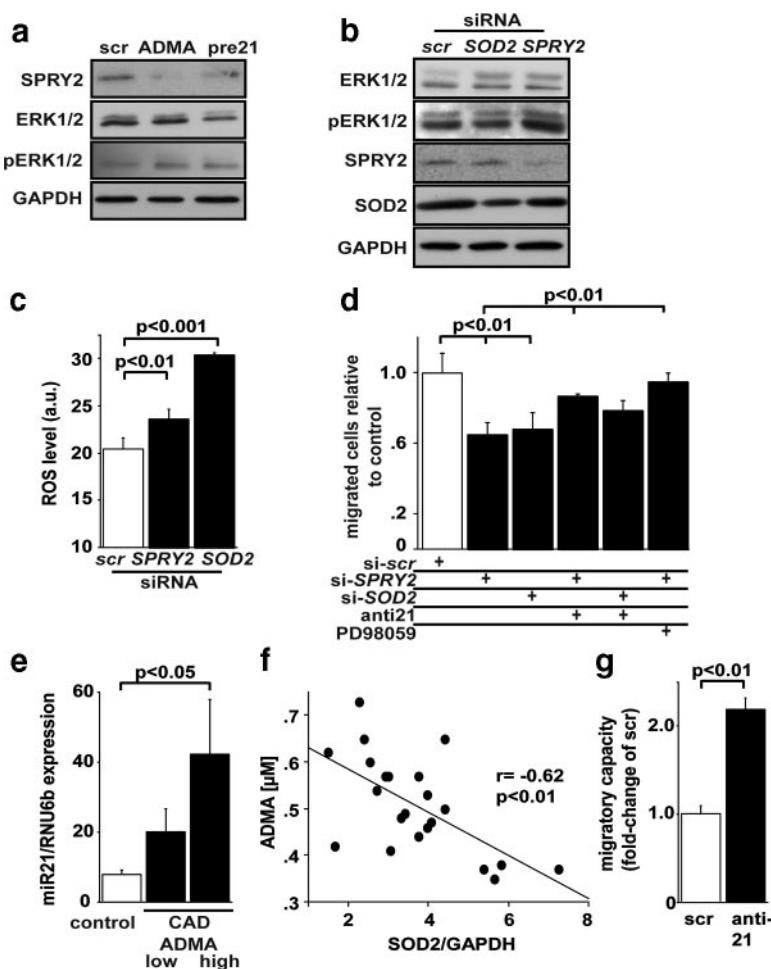

Figure 3. MiR-21-dependent mechanisms leading to APC dysfunction in vitro and in patients with coronary artery disease. **a**, Protein expression of the Erk Map kinase inhibitor SPRY2, ERK1/2, phospho-ERK1/2 (pERK1/2), and GAPDH after treatment of APCs with ADMA (1 μmol/L, 24 hours) or transfection with *miR-21* precursors (100 nmol/L, 72 hours). **b**, Protein expression of SPRY2, ERK1/2, pERK1/2, SOD2, and GAPDH after transfection of siRNAs against SOD2 or SPRY2. **c**, ROS formation and migratory capacity (**d**) of APCs transfected with scrambled siRNAs or siRNAs against SPRY1 or SOD2. Additionally, effects of *miR-21* blockade (anti-21) and Erk Map kinase inhibition (PD98059) on migratory capacity are shown. **e**, *miR-21*/RNU6b expression levels in control subjects and patients with CAD and high (>0.55 μmol/L) or low (<0.55 μmol/L) ADMA plasma levels. Patient information is shown in Online Table III. **f**, Correlation of ADMA plasma levels and SOD2 expression in APCs isolated from patients with CAD. **g**, Migratory capacity of APCs from patients with CAD and high ADMA plasma levels 72 hours after transfection with scrambled (scr) or *miR-21* inhibitors (anti-21). Data are expressed as means ± SEM, n=3 to 8 per experiment/group.

ADMA-mediated and *miR-21*-mediated ROS increase (Figure 2g) as well as normalization of migratory capacity (Figure 2h). Interestingly, the effects of ADMA and *miR-21* were at least in part dependent on the Erk Map kinase signaling pathway based on inhibition experiments with PD98059 (Figure 2g and 2h). In line, ADMA and *miR-21* decreased the Erk Map kinase inhibitor Sprouty2 (SPRY2), leading to enhanced ERK1/2 phosphorylation (Figure 3a). We next tested whether small interfering (si)RNA-mediated reduction in SOD2 or SPRY2 expression would mimic the effects of *miR-21* (Figure 3b). Of note, SPRY2 reduction by siRNA also resulted in increased ERK1/2 phosphorylation (Figure 3b). Comparable to the effects of *miR-21*, the reduction of SPRY2 or SOD2 increased ROS formation and impaired APC migratory capacity (Figure 3c and 3d). Impaired migration of SPRY2-deficient APCs could be completely normalized by Erk Map kinase inhibition but only partly by cotreatment with anti-*miR-21*. The effect of siRNA-mediated SOD2 reduction on APC migration could not be rescued by *miR-21* blockade (Figure 3d), suggesting important roles of SPRY2 and SOD2 in *miR-21*-mediated APC dysfunction.

MiR-21 Activation in APCs From Patients With CAD

To translate the in vitro findings into a clinical scenario, we isolated APCs from patients with angiographically proven

CAD as well as control subjects (no CAD, see Online Table III) and determined ADMA plasma levels, *miR-21* expression, and APC function. APCs from CAD patients with high ADMA plasma levels showed significantly increased *miR-21* expression levels compared with patients with low ADMA levels or control subjects (Figure 3e). *MiR-21* expression of isolated APCs significantly correlated with ADMA plasma levels ($r=0.57$, $P<0.01$) and inversely with migratory capacity ($r=-0.56$; $P\leq0.05$). ADMA plasma levels inversely correlated with SOD2 expression in APCs ($r=-0.62$; $P<0.01$; Figure 3f) as determined in a subgroup of an independent study population with CAD.⁴ To study a functional role of increased *miR-21* levels in APC dysfunction of CAD patients, we performed further ex vivo studies. We transfected APCs from CAD patients with *miR-21* inhibitors or scrambled controls and investigated APC migratory capacity. Blockade of *miR-21* by anti-*miR-21* but not by scrambled controls normalized APC function of CAD patients (Figure 3g), identifying *miR-21* as a potential therapeutic target in dysfunctional APCs.

Discussion

ADMA inhibits the enzyme activity of NOSs and contributes to CAD.^{3,6} In this study, we show a further ADMA-mediated mechanism leading to increased oxidative stress and impaired NO bioavailability in APCs, which play a key role in

endothelial regeneration and vascular homeostasis.⁷ We identified *miR-21* to be activated by ADMA and to reduce the expression of superoxide dismutase 2, a key enzyme in oxidative stress defense. In addition, *miR-21* led to oxidative stress by Erk Map kinase activation caused by inhibition of SPRY2. This resulted in impairment of NO availability and APC dysfunction. The in vitro data could be translated into APCs from patients with CAD and high ADMA plasma levels. Treatment with *miR-21* inhibitors rescued APC function in vitro and ex vivo. Recently, a further report found ADMA to result in increased superoxide production in endothelial cells.¹⁷

Because APC dysfunction is mechanistically involved in the onset and progression of endothelial dysfunction and coronary artery disease, specific therapies targeting dysfunctional APCs may be of great clinical value. Indeed, previous studies have suggested that miRNAs may serve as valuable therapeutic targets in a variety of diseases including cardiovascular disease.^{14,15,18,19} For instance, antagonism of *miR-21* has been shown to reduce cardiac fibrosis by a direct effect in cardiac fibroblasts¹⁴ and to prevent vascular neointima proliferation after carotid damage.²⁰ In this study, we show that *miR-21* is also expressed in APCs and that its inhibition reduced ADMA-mediated oxidative stress and improved cellular migratory capacity. *MiR-21* thus emerges as an interesting target in various forms of cardiovascular diseases.

Our study has several limitations: we focused only on APCs characterized as described in the Online Data Supplement and thus it remains to be determined whether the *miR-21*-dependent mechanism also contributes to dysfunction of other subtypes of vascular progenitor cells. Also, there may be additional mechanisms involved in how ADMA leads to APC dysfunction, such as endothelial NOS uncoupling²¹ or activation of NADPH oxidases.¹⁷ There are probably many more direct and indirect targets of *miR-21* in APCs that must be uncovered in future studies. However, our data point to a role of *miR-21* in regulation of oxidative stress defense in APCs and identify *miR-21* as a potential therapeutic target in patients with CAD to improve impaired APC function.

Novelty and Significance

What Is Known?

- MicroRNAs are regulatory RNA molecules and key players in vascular differentiation and endothelial function.
- Asymmetrical dimethylarginine (ADMA) is an endogenous nitric oxide synthase inhibitor and contributes to endothelial dysfunction and cardiovascular death.
- MicroRNAs emerge as potential powerful therapeutic targets in cardiovascular disease.

What New Information Does This Article Contribute?

- ADMA regulates microRNAs in circulating angiogenic cells.
- ADMA-mediated increase of *miR-21* triggers oxidative stress and dysfunction in circulating angiogenic cells via repression of the Erk Map kinase inhibitor Sprouty-2 and superoxide dismutase 2.
- Targeting *miR-21* rescues ADMA-mediated circulating angiogenic cell dysfunction *in vitro* and improves functional activity of

proangiogenic cells isolated from patients with coronary artery disease.

ADMA levels are increased in patients with coronary artery disease and contribute to endothelial and angiogenic progenitor cell dysfunction and cardiovascular mortality. MicroRNAs post-transcriptionally regulate about one third of genes and play a major role in endothelial homeostasis and function. We show microRNAs to be altered in dysfunctional angiogenic progenitor cells (circulating angiogenic cells). ADMA increased *miR-21*, which resulted in oxidative stress and dysfunction of angiogenic progenitor cells. *MiR-21* antagonism normalized the function of patient-derived circulating angiogenic cells and may serve as a valuable target for the development of future microRNA-based therapeutic treatment strategies for cardiovascular disease.

Supplementary Detailed Methods

Isolation, characterization and culture of angiogenic progenitor cells (APC) and endothelial cells

We isolated angiogenic progenitor cells (APC) from healthy volunteers or coronary artery disease patients as described¹. Briefly, peripheral blood mononuclear cells (PBMCs) were isolated by placing whole blood samples on Ficoll® tubes (Amersham) with subsequent centrifugation at 2100 rpm for 20 min. The supernatant was then removed and the interphase was resuspended in 10 ml phosphate buffered saline (PBS) with 2 mM ethylenediaminetetraacetic acid (EDTA). Again, cells were centrifuged at 1200 rpm, supernatant removed and the cell pellet containing PBMCs was seeded on fibronectin coated 6-wells in EBM-2 culture medium supplemented with EGM SingleQuots (Cambrex, UK) and 20% fetal calf serum (FCS) for 4 days. To exclude contamination with mature circulating endothelial cells, we carefully removed culture supernatants 2h after initial seeding and placed non-adherent cells to new fibronectin-precoated wells. This procedure leads to peripheral-blood derived cells with angiogenic properties. Classification schemes and nomenclature of such cells varies in the literature. Most groups name those cells as “early outgrowth EPC”, “EPC”, “monocytic EPC”, “circulating angiogenic cells (CAC)” or “APC”. APC were characterized by cellular uptake of acetylated LDL (dil-acLDL; Molecular Probes, Eugene, USA), binding of fluorescein isothiocyanate (FITC)-conjugated lectin from Ulex europeus (UEA-1; Sigma, Germany), expression of vascular endothelial growth factor receptor-2 (VEGFR-2), von Willbrand factor (vWF) and endothelial nitric oxide syntase (eNOS), capacity for integration during endothelial tube formation, cellular migration and colony forming unit (CFU) capacity, as described by us previously¹⁻³. Human umbilical vein endothelial cells (HUVECs) and human coronary arterial endothelial cells (HCAECs) were obtained from Lonza (Germany) and cultured until subconfluence before use.

Cellular migration assays

Modified Boyden chamber assays

Migratory capacity of APC was investigated using the modified Boyden chamber assay as described previously¹. In brief, APC (1×10^4) were cultured in inlets (Falcon HTS Fluoro Blok insert, 8-μm pore size), which were placed in 24-well culture dishes containing endothelial basal medium (Clonetics, Germany) and 50 ng/mL VEGF, and 100 ng/mL stromal cell-derived factor (SDF)-1 to measure APC migratory capacity. After 24h, migrated cells on the bottom of the membrane were stained with dil-acLDL and counted manually using fluorescence based microscopy evaluation¹.

Scratch wound assays

Additionally, migratory capacity of APC was measured by scratch wound assays. APC were cultured in 24-well plates, transfected for 72h with miR-21 precursors or scrambled controls, stained with Dil-acLDL and photographs were taken directly after and 4h after creating a scratch wound in a confluent monolayer with a 10- μ l tip. The width of the wound was measured using AxioVision software (Zeiss, Germany).

RNA isolation

Total RNA (including miRNAs) was isolated using Trizol (Invitrogen, Germany). Briefly, pellets were dissolved in Trizol reagent for five minutes, chloroform was added and centrifuged at 12000 g for 15 min. The supernatant was conveyed and isopropanol added. A centrifugation step followed for 15 min at 12000g after incubation for 10 min. The precipitated RNA was washed in 75% ethanol and dissolved in RNase-free water. For microarrays, RNA was isolated using the *mirVana* miRNA Isolation Kit (Ambion) following the company's protocol.

MiRNA microarrays

After isolation of total RNA we purified miRNAs using the flashPAGE Fractionator system (Ambion) as described by the manufacturer. Capillary electrophoresis (Bioanalyzer 2100; Agilent) was used to assess quality of total RNA and purity of isolated miRNAs. miRNA obtained from 10 μ g total RNA was labeled with the dye Cy3 (Molecular Probes, Carlsbad, Calif) with the use of the *mirVana* miRNA Labeling Kit (Ambion) according to the manufacturer's recommendations. Each target was hybridized to a separate array (n=3-4 for each group: APC, APC treated with ADMA (1 μ M for 24h), HUVECs, HCAECs). Microarrays with a set of 464 miRNAs (*mirVana* miRNA Probe Set, Ambion; including 312 different human miRNAs) were spotted in-house on SCHOTT Nexterion Slide E microarray slides in quadruplicate. The oligonucleotide probes were 42 to 46 nucleotides long and consisted of an 18- to 24-nucleotide segment that targeted a specific known human, mouse, or rat miRNA. A complete listing of the probes in the probe set can be found at www.ambion.com/techlib/resources/miRNA_array/index.html. Slide processing, miRNA purification and enrichment, and labeling were performed according to the Ambion *mirVana* manuals (www.ambion.com/techlib/prot/). Data acquisition was done with the use of ScanAlyze Software (M. Eisen, LBNL). Scanned raw data (see Online Table I left) were normalized using the *vsn* package in R. Each array data was subjected to an affine transformation, then the whole data were transformed by a variance-stabilizing transformation using a *glog* (generalized logarithm) function. *glog* is like the natural logarithm for large values (large compared to the background noise), but is less steep for smaller values. Row data after normalization raised to the power on the base of the natural logarithm are shown on the right of Online Table I. Expression of various miRNAs was validated by specific miRNA stem loop primer reverse transcription followed by TaqMan RT-PCR analyses (see below).

MicroRNA Stem Loop RT-PCR and SYBR Green mRNA RT-PCR

Expression of several miRNAs was validated by quantitative miRNA stem loop RT-PCR technology (TaqMan MicroRNA Assays, Applied Biosystems, Foster City, Calif). All miRNA samples were derived from isolations having the same total RNA concentration. We used highly target-specific stem loop structure and reverse transcription primer, and after reverse transcription used specific TaqMan hybridization probes for miRNA amplification. This allows high specificity for only the mature miRNA target and formation of a reverse transcription primer/mature miRNA

chimera, extending the 5' end of the miRNA. The small RNA molecule U6 small nuclear (RNU6-2 or RNU6b) was amplified as a control.

For detection of SOD2 mRNA expression levels we used a realtime SYBR Green-based approach. In detail, after RNA isolation we performed reverse transcription (iScript cDNA synthesis kit, Bio-Rad, Germany) and then used the iQ SYBR Green Supermix (Bio-Rad, Germany) and the following oligonucleotides for SOD2 amplification: fwd- 5'CAAATTGCTGCTTGTCCAAA3', rev- 5'TCTCCCAGTTGATTACATTCCA3'. Data were normalized to GAPDH expression.

MiRNA transfection

APC were transfected with precursor and inhibitors of miR-21 (50–100nM, Ambion) using Lipofectamin 2000 (Invitrogen) as described⁴.

Detection of reactive oxygen species (ROS) and nitric oxide (NO) levels in APC

We used a flow cytometry-based method with the substrates dihydroethidium (DHE, 2.5 µM; Molecular Probes) to detect ROS as described² and diaminofluorescein-2 diacetate (DAF-2/DA) to detect NO levels. For NO detection, we incubated APC (0.5 × 10⁶ cells) for 1h with 10µM DAF-2/DA. FACS analysis (FACSCalibur, Becton Dickinson) was performed immediately after trypsinising and suspending the cells in PBS.

Proteome profiling and Western blotting

HUVECs and APCs were treated with miR-21 precursors or scrambled controls (each 100 nM) for 72h before proteome analysis. Key proteomic techniques involved adaptations of previously published protocols, including difference in-gel electrophoresis (DIGE) and tandem mass spectrometry⁵ (see below). Protein lysates were prepared as described¹. We used primary antibodies against superoxide dismutase 2 (SOD2, ab16956, Abcam, Germany), sprouty-2 (SPRY2, ab50317, Abcam, Germany), ERK1/2 (9102, Cell Signaling, Germany), phospho-ERK1/2 (9101, Cell Signaling, Germany) and glyceraldehyde dehydrogenase (GAPDH, ab8245, Abcam, Germany), as well as appropriate secondary antibodies.

Two dimensional difference gel electrophoresis (2D-DIGE)

Cell monolayers were rinsed thoroughly with cold PBS to remove any serum components. Protein extracts were prepared using a lysis buffer (8M urea, 4% w/v CHAPS, 30mM Tris-Cl, pH 8.5) compatible with DIGE labelling (GE Healthcare). After centrifugation at 13,000 g for 10 min, the supernatant containing soluble proteins was harvested and the protein concentration was determined using a modification of the method described by Bradford⁶. The fluorescence dye labelling reaction was carried out at a dye/protein ratio of 200pmol/50µg⁷. After incubation on ice for 30 min, the labelling reaction was stopped by scavenging non-bound dyes with 10mM lysine (L8662, Sigma) for 15 min. For two-dimensional gel electrophoresis, samples were mixed with 2x buffer (8M urea, 4% w/v CHAPS, 2% w/v DTT, 2% v/v Pharmalytes 3-10 for IEF), 50µg per sample were diluted in rehydration solution (8M urea, 0.5% w/v CHAPS, 0.2% w/v DTT, and 0.2% v/v Pharmalyte pH 3-10) and loaded on IPG strips (18cm, pH 3-10, nonlinear, GE healthcare). After rehydration overnight, strips were focused at 0.05 mA/IPG strip for 28 kVh at 20°C (IPGphor, GE healthcare). Once IEF was complete the strips were equilibrated in 6M urea containing 30% v/v glycerol, 2% w/v SDS and 0.01% w/v Bromphenol blue, with addition of 1% w/v DTT for 15 min, followed by the same buffer without DTT, but with the addition of 4.8% w/v iodoacetamide for 15 min. SDS-

PAGE was performed using 12% T (total acrylamide concentration), 2.6% C (degree of cross-linking) polyacrylamide gels without a stacking gel, using the Ettan DALT system (GE healthcare). The second dimension was terminated when the Bromophenol blue dye front had migrated off the lower end to the gels. After electrophoresis, fluorescence images were acquired using the Ettan DIGE imager (GE healthcare). Finally, gels were fixed overnight in methanol: acetic acid: water solution (4:1:5 v/v/v). Protein profiles were visualised by silver staining using the Plus one silver staining kit (GE healthcare) with slight modifications⁸ to ensure compatibility with subsequent mass spectrometry analysis. For documentation, silver-stained gels were scanned in transmission scan mode using a calibrated scanner (GS-800, Bio-Rad). DIGE gels were analysed using the Decyder software (Version 6.5, GE healthcare). All 2-DE gels were of high quality in terms of resolution as well as consistency in spot patterns. Spots exhibiting expression change above 1.2 fold between two groups and a statistical difference ($p<0.05$) were excised for identification. A detailed methodology is available on our website <http://www.vascular-proteomics.com>.

Nano-LC MS/MS

In-gel digestion with trypsin was performed according to published methods⁹ modified for use with an Investigator ProGest (Genomic Solutions) robotic digestion system. Following enzymatic degradation, samples were separated by liquid chromatography on a reverse-phase column (C18 PepMap100, 3 μ m, 100Å, 25 cm, Dionex) and applied to a LTQ Orbitrap XL mass spectrometer (Thermo Scientific). Spectra were collected from the mass analyzer using full ion scan mode over the m/z range 300-2000. Six dependent MS/MS scans were performed on each ion using dynamic exclusion. Spectra were collected from the Orbitrap mass analyzer using full ion scan mode over the mass-to-charge (m/z) range 450-1800. MS-MS scans were performed on each ion using dynamic exclusion.

Data Analysis of proteome data

Database searches were performed using the TurboSEQUEST software (Bioworks Browser version 3.3.1, Thermo Fisher) against human database (19804 protein entries, UniProtKB Release 13.5, 10-Jun-2008) using following parameters: parent tolerance 1.5 Da, fragment tolerance 1.0 Da, carbamidomethylation of cysteine as fixed modification, oxidation of methionine as variable modification, maximum missed cleavage: 2. Following filter was applied: for charge state 1, $X_{\text{corr}} > 1.5$; for charge state 2, $X_{\text{corr}} > 2.0$; for charge state 3, $X_{\text{corr}} > 2.5$. Search results were loaded into Scaffold software (version 2.0, Proteome Software) and calculated with X!Tandem. Following filters were applied: peptide probability > 95%, protein probability > 99%, minimum No. of peptides per protein: 2.

Study subjects and determination of ADMA plasma levels

Approval from the ethical committee of the University of Würzburg was obtained, as was informed written consent from patients. Patients admitted to hospital because of stable angina with subsequent coronary angiography were enrolled. Only patients with documented coronary artery disease (2- or 3-vessel disease) were included (see also Online Table III for further patient characteristics). APC were isolated and cultured as described above. ADMA plasma levels were determined as described¹⁰.

Statistical analysis

Data are expressed as means \pm SEM. Statistical analysis was performed by one-way

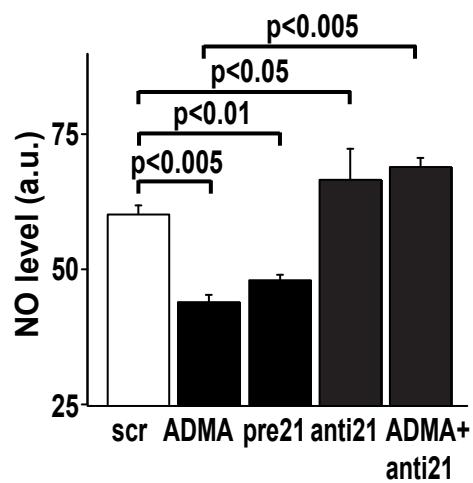

ANOVA followed by multiple comparisons using Fisher's protected least significant difference test. To analyze relationships between variables simple regression analyses were performed. Statistical analysis was performed using StatView 5.0 statistic program (Abacus Concepts, Berkley, CA). Statistical significance was assumed at $P \leq 0.05$.

APC= angiogenic progenitor cells

HUVEC, human umbilical vein endothelial cells

HCAECs, human coronary artery endothelial cells

Scanned data were normalized using the vsn package in R (see Supplemental Online Methods).

Row data after scanning (top; raw data) and after normalization raised to the power on the base of the natural logarithm are shown (bottom; normalized data).

Online Table II) Deregulated proteins based on a proteome approach

Protein name	accession numbers	No.on Gel	Av. Ratio	p-value
downregulated proteins by miR-21 overexpression (miR-21 precursor group / scrambled miR group)				
Superoxide dismutase [Mn]				
SPARC precursor	SODM_HUMAN	1925	-1,47	0,001900
Beta-2-microglobulin precursor	SPRC_HUMAN	989	-1,38	0,000016
Heat shock cognate 71 kDa protein	B2MG_HUMAN	2442	-1,37	0,000470
BTB/POZ domain-containing protein KCTD12	HSP7C_HUMAN	459	-1,35	0,000140
Unidentified	KCD12_HUMAN	1328	-1,34	0,000005
-	-	2435	-1,34	0,000460
Annexin A6	ANXA6_HUMAN	458	-1,31	0,000650
Vimentin	VIME_HUMAN	2554	-1,3	0,000270
Reticulocalbin-1 precursor	RCN1_HUMAN	2554	-1,3	0,000270
Endoplasmin precursor	ENPL_HUMAN	144	-1,28	0,000024
Protein disulfide-isomerase A3 precursor	PDIA3_HUMAN	692	-1,28	0,000053
Calreticulin precursor	CALR_HUMAN	667	-1,27	0,000390
NADH-ubiquinone oxidoreductase 75 kDa subunit	NDUS1_HUMAN	336	-1,25	0,004600
Vimentin	VIME_HUMAN	592	-1,25	0,000160
Calumenin precursor	CALU_HUMAN	881	-1,25	0,001600
Protein disulfide-isomerase A3 precursor	PDIA3_HUMAN	693	-1,25	0,000200
Nuclear autoantigenic sperm protein	NASP_HUMAN	480	-1,24	0,000780
Guanine nucleotide-binding protein subunit beta-2-like 1	GBLP_HUMAN	1484	-1,24	0,003700
Actin-related protein 2/3 complex subunit 2	ARPC2_HUMAN	1484	-1,24	0,003700
Lamin-B2	LMNB2_HUMAN	466	-1,23	0,000770
Xaa-Pro dipeptidase	PEPD_HUMAN	757	-1,23	0,001700
Protein disulfide-isomerase A3 precursor	PDIA3_HUMAN	689	-1,22	0,000014
Protein disulfide-isomerase precursor	PDIA1_HUMAN	620	-1,21	0,000013
Elongation factor 2	EF2_HUMAN	224	-1,21	0,002000
Programmed cell death 6-interacting protein	PDC6I_HUMAN	224	-1,21	0,002000
Early endosome antigen 1	EEA1_HUMAN	33	-1,2	0,013000

Annexin A6
 Calreticulin precursor
 Thioredoxin domain-containing protein 5 precursor
upregulated proteins by miR-21 overexpression
(scrambled miR group / miR-21 precursor group)

Cofilin-1
 Ezrin
 Proliferating cell nuclear antigen
 Proteasome subunit beta type-6 precursor
 Profilin-1
 NHP2-like protein 1
 L-lactate dehydrogenase A chain
 Eukaryotic translation initiation factor 3 subunit J
 Inorganic pyrophosphatase
 Proto-oncogene C-crk
 Enoyl-CoA hydratase, mitochondrial precursor
 Transcription factor BTTF3 homolog 4
 Non-POU domain-containing octamer-binding protein
 Cathepsin D precursor
 L-lactate dehydrogenase A chain
 40S ribosomal protein S3
 Carbonyl reductase [NADPH] 1
 S-formylglutathione hydrolase
 Mitochondrial 28S ribosomal protein S6
 Myotrophin
 Radixin
 Lamin-A/C
 Unidentified
 GTP:AMP phosphotransferase mitochondrial
 40S ribosomal protein S3
 NAD(P)H dehydrogenase [quinone] 1
